Laparoscopic Cholecystectomy in a Patient with Inversion of the Abdominal Cavity

ABSTRACT

Situs viscerum inversus totalis is a rare condition in which organs are transposed from the normal side to the opposite side in the abdominal and chest cavity. It occurs in a ratio from 1:5000 to 1:20000. In this case report, a case of a 50-year-old man who was diagnosed with the symptomatic presence of gallstones with the usage of ultrasound. The patient underwent the laparoscopic cholecystectomy, the surgical procedure lasted for 90 minutes, it was successfully completed and the patient was discharged on the first postoperative day. (SrC Med 2017:48:145-147)

Introduction

Situs viscerum inversus totalis is characterized by the transposition of main organs of the chest and all the internal organs of the abdominal cavity to the side opposite to the normal position in the body. The liver and gallbladder are located on the left side, while the stomach and spleen on the right. Normal organogenesis requires a 270 degree rotation in the direction opposite to the clockwise direction, which gives a normal anatomy. In situs inversus totalis, a 270 degree rotation is in the clockwise direction.1 The incidence of situs viscerum inversus ranges from 1 to 5000 to 1 at 20000.2,3 Thus, the stomach and spleen are located on the right side (Picture 1.) and liver and gallbladder on the left (Picture 2.).

A ratio between the occurrence in sexes is 1:1, and there is no racial inclination. This condition can be associated with cardiac anomalies as well as with Kartagener’s syndrome (bronchiectasis, sinusitis, situs inversus).2,4 There are no data suggesting the increased incidence of gallstones in patients with situs inversus totalis.5 The first case of situs viscerum inversus was described by Fabricius in 1600.1 This phenomenon has been known to be present in animals since the time of Aristotle.2 The first known laparoscopic cholecystectomy in patients with situs inversus was published by Campos and Sipes in 1991.2 Due to the nature of the reverse organ arrangement and possible joint anomalies, the surgery is quite demanding, even for an experienced surgeon.2,3

Picture 1. Part of the Stomach Seen on the Right
was right. It is common during the operation that the surgeon takes a disorder with his right hand, and the assistant keeps the gallbladder neck with a grip on the central axillary line. The arthritis of the cystic and the ductus cysticus were doubly individually clipped with titanium clips, while the gallbladder was removed from its place by an anterograde route. The operation lasted for 90 minutes and was successfully completed (Figure 3).

**Figure 3. Arrangement of Incisions on the Abdominal Wall**

On the first postoperative day, the active drainage set during the surgery was taken out and the patient was discharged for home treatment.

**Discussion**

Situs inversus totalis is a very rare condition, and successful laparoscopic cholecystectomy in these patients is even rarer. In July 2006, Bediou published the 13th case in the world. None of these cases was from Bosnia and Herzegovina. In our case, both surgeons had a dominant right hand. The modifications in the technique were also described in a way that the assistant holds the gallbladder neck with the grip, while the surgeon prepares elements of the Calot’s triangle with the right hand, which happened in some segments during our operation. Arya and associates published a paper in which he described how he performed a laparoscopic cholecystectomy with situs viscerum inversus with two assistants, and the arrangement of ports he used was the same as in our case. The difference with regard to his approach was that he had an assistant more in relation to us, who stood by the operator and held the gallbladder neck with the grip. Furthermore, there is a description in literature regarding the modification where the patient was in a position with his legs in abduction (Lloyd-Davis) and where the operator was between the patient’s legs, which
was not our method of choice.9

Conclusion
A surgeon with a dominant right hand should prepare the elements of Calot’s triangle with his right hand without using his left hand.

It is much easier for a surgeon whose dominant side is left to perform laparoscopic cholecystectomy in patients with situs viscerum inversus totalis.

**Laparoskopska holecistektomija kod pacijenta sa inverzijom organa trbušne duplje**

**SAŽETAK**

Slično situs viscerum inversus totalis je rijetko stanje kod koga su organi transpozicionirani sa normalne strane na suprotnu stranu u trbušnoj i grudnoj duplji. Javlja se od 1:5000 do 1:20000. U prikazu slučaja, radi se o muškarcu starama 50 godina, kod koga je ultrazvučno dijagnostikovano simptomatsko pripuštenje karinca u žućnoj kesi. Podvrnuto je laparoskopskoj holecistektomiji, operativni zahvat je trajao 90 minuta, te je uspješno završen, a pacijent je otpušten kći prvog postoperativnog dana.
